An introduction to Stan

A programming language for Bayesian modeling

Trung Dung Tran and Emmanuel Lesaffre

Rijksinstituut voor Volksgezondheid en Milieu The Netherlands

June 2018

Objectives

- Know Stan and intuitively understand its algorithm(s).
- Learn Stan programming language.
- Write a simple Bayesian model using Stan language and run in R via Rstan interface.
- Do posterior inferences.
- Know some differences between Stan and BUGS.
- Know where to ask for help.

Topic of today

 This presentation focuses on practical aspect of the language in relation with R.

Theoretical aspect is very briefly mentioned.

 Stan can be used for solving differential equations, but today is only for statistical modeling.

- Summary

What is Stan

- A high level and imperative probabilistic programming language.
 - ▶ Imperative: order is a matter.
 - ▶ Probabilistic programming language: C++ behind the scene.
- Users are easily to specify statistical models.
- Stan uses the No-U-Turn sampler as default, an adaptive variant of Hamiltonian Monte Carlo (HMC) algorithm (Hoffman and Gelman, 2014).

Motivation

• Efficiently sample from high-dimensional parameter space (Hoffman and Gelman, 2014).

A responsible and supporting team: http://mc-stan.org/

• An active discussion group: http://discourse.mc-stan.org/

 An extensive manual (stan-reference-2.17.0.pdf, download from http://mc-stan.org/).

Algorithm(s)

HMC algorithm (Neal, 2012)

- Target density: $p(\theta|y)$ (for short $p(\theta)$) for parameters θ .
- Auxiliary momentum variable: $\rho \sim MultiNormal(0, \Sigma)$.
- Joint density: $p(\rho, \theta) = p(\rho|\theta)p(\theta)$.
- Define a Hamiltonian:

$$\begin{split} H(\rho,\theta) &= -\mathrm{log}p(\rho,\theta) = -\mathrm{log}p(\rho|\theta) - \mathrm{log}p(\theta) \\ &= T(\rho|\theta) + V(\theta) = \text{"kinetic energy"} + \text{"potential energy"}. \end{split}$$

- Generating transitions from the current θ :
 - $ightharpoonup
 ho \sim MultiNormal(0, \Sigma)$
 - ▶ The pair (ρ, θ) "uniquely" evolves via Hamilton's equations:

$$\frac{d\rho}{dt} = -\frac{\partial V}{\partial \theta}$$

$$\frac{d\theta}{dt} = +\frac{\partial T}{\partial \rho}$$

Algorithm(s)

- Unfortunately, we cannot solve the system analytically.
- Numerical approximation for the Hamiltonian systems: Leapfrog integrator.
- Correcting for numerical errors: Metropolis acceptance step.
- The probability of accepting the proposal $(\rho^*; \theta^*)$ generated by transitioning from (ρ, θ) is

$$\min(1, exp(H(\rho, \theta) - H(\rho^*; \theta^*))).$$

- In summary, HMC algorithm steps:
 - Start at an initial state for θ .
 - Propose a new θ : at a given iteration, sample a new ρ , propose θ using leapfrog integrator with discretization time ε and number of steps L.
 - ► Acceptance step: updating to the new state or keeping the current one.

Algorithm(s)

No-U-Turn sampler (NUTS)

- Discretization time ε (step size), number of steps L, and Σ are required in HMC algorithm.
- No-U-Turn sampler
 - ightharpoonup automatically optimizes arepsilon
 - ightharpoonup dynamically adapts L, and
 - ightharpoonup estimates Σ .
- Optimizing ε uses dual averaging (Nesterov, 2009), depending on the following.

parame	eter	description	constraint	default
δ		target Metropolis acceptance rate	$\delta \in [0,1]$	0.80
γ		adaptation regularization scale	$\gamma > 0$	0.05
K		adaptation relaxation exponent	$\kappa > 0$	0.75
t_0		adaptation iteration offset	$t_0 > 0$	10

• Sometimes δ needs to be changed (more precisely increased).

- User:
 - ▶ Define $p(\theta|y)$ using Stan language.

- User:
 - ▶ Define $p(\theta|y)$ using Stan language.
 - ► Choose the algorithm (NUTS is default).

- ▶ Define $p(\theta|y)$ using Stan language.
- ► Choose the algorithm (NUTS is default).
- (Optional) initialize initial values.

- ▶ Define $p(\theta|y)$ using Stan language.
- Choose the algorithm (NUTS is default).
- (Optional) initialize initial values.
- Occasionally, adjust default values of the algorithm parameters (when observing pathologies (Stan often highlights)).

- ▶ Define $p(\theta|y)$ using Stan language.
- Choose the algorithm (NUTS is default).
- (Optional) initialize initial values.
- Occasionally, adjust default values of the algorithm parameters (when observing pathologies (Stan often highlights)).
- Select number of chains and iterations (including warm-up).

- ▶ Define $p(\theta|y)$ using Stan language.
- Choose the algorithm (NUTS is default).
- (Optional) initialize initial values.
- Occasionally, adjust default values of the algorithm parameters (when observing pathologies (Stan often highlights)).
- Select number of chains and iterations (including warm-up).
- Machine:
 - Initialize the initial values (if not done yet).

User:

- Initialize the initial values (if not done yet).
- Optimize the algorithm through the warm-up period.
- Sample the parameters.

- Introduction to Stan
- 2 A Stan program
- Stan blocks
- 4 Stan syntax
- 5 More about Rstan and related packages
- 6 Before writing the first program
- Working with some statistical models
- 8 Coding with missing values
- Summary

An example: A linear regression model

(i) Fit a simple linear regression model with y as the response, x as a covariate, and N as the sample size. (ii) After that check the model using PPC with the skewness discrepancy

$$\frac{\sum_{i=1}^{N}((y_i-\overline{y})/s)^3}{N}$$

where \overline{y} and s are sample mean and standard deviation resp. Solution (i):

- We are given the data: y, x, and N.
- We need to estimate the parameters, β and σ , using the following model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

The linear model

Stan program

```
data {
    int<lower=1> N; // sample size
    vector[N] y; // response
    vector[N] x; // covariate
}
parameters {
    vector[2] beta; // regression coefficients
    real<lower=0> sigma; // SD
}
model {
    beta ~ normal(0, 1000); // prior
    sigma ~ cauchy(0, 5); // half-cauchy implicitly
    for (i in 1:N) {
        y[i] ~ normal(beta[1] + beta[2] * x[i], sigma);
```

Blocks

Blocks

Block	Example		
data transformed data	Observed responses, covariates Sample mean		
parameters	Parameters, missing values		
transformed parameters	SD as the squared root of a variance		
model	$y \sim N(\mu, \sigma)$		
generated quantities	Replicate of the response		

- The components are written in that order.
- Sometimes, a functions block defining user's functions is added before the data block.

Working with R

Call Stan.

```
library(rstan)
options(mc.cores = parallel::detectCores())
rstan_options(auto_write = TRUE)
```

• Prepare data for the data block.

```
data1a = list(N = N, x = x, y=y)
```

- (Optionally) provide initial values.
- Run Stan.

```
model1a = stan(file="model1a.stan", data = data1a,
iter=1000, chains = 4, pars = c('beta', 'sigma'))
```

- Occasionally, adjust algorithm parameters.
- Process output (in R or using Shiny).
- See rstan document (rstan.pdf) for more detail.

The folder Ex1 contains a Stan program where the code is correct except the order of the blocks.

Run R and get the meaning of the warning(s).

The folder Ex1 contains a Stan program where the code is correct except the order of the blocks.

• Run R and get the meaning of the warning(s).

The folder Ex1 contains a Stan program where the code is correct except the order of the blocks.

Run R and get the meaning of the warning(s).

- Open model_Ex1.stan. Press Ctrl + G and enter the line number to locate the line with error.
- Why is beta in the code (line 13) but Stan says it does not exist?

 Even beta does exist in line 13, prior to line 4, no definition or declaration of beta exists.

Put the parameters block before the model block.

Now N does not exist before its first use.

• Adjust the code following the message(s) until being correct.

- Summary

Data block

The model:

$$\mathbf{y_i} \sim N(\beta_1 + \beta_2 \times \mathbf{x_i}, \sigma^2) \quad \forall i = 1, ..., N$$

Data block:

Only declaration, no statement.

Data block

The model:

$$\mathbf{y_i} \sim N(\beta_1 + \beta_2 \times \mathbf{x_i}, \sigma^2) \quad \forall i = 1, ..., N$$

• Data block:

- ▶ Only declaration, no statement.
- ▶ Values are assigned from the interface, e.g. Rstan.

Data block

The model:

$$\mathbf{y_i} \sim N(\beta_1 + \beta_2 \times \mathbf{x_i}, \sigma^2) \quad \forall i = 1, ..., N$$

Data block:

- Only declaration, no statement.
- ▶ Values are assigned from the interface, e.g. Rstan.
- Constraints for checking.

Computation of the sample mean and standard deviation: \overline{y} and s.

Transformed data block:

```
transformed data {
    real mean_y;
    real<lower=0> sd_y;
    mean_y = mean(y);
    sd_y = sd(y);
}
```

▶ Declaration and definition of 'constants'.

Computation of the sample mean and standard deviation: \overline{y} and s.

Transformed data block:

```
transformed data {
    real mean_y;
    real<lower=0> sd_y;
    mean_y = mean(y);
    sd_y = sd(y);
}
```

- Declaration and definition of 'constants'.
- Not reading from an external source.

Computation of the sample mean and standard deviation: \overline{y} and s.

Transformed data block:

```
transformed data {
    real mean_y;
    real<lower=0> sd_y;
    mean_y = mean(y);
    sd_y = sd(y);
}
```

- Declaration and definition of 'constants'.
- Not reading from an external source.
- Assignments are only allowed to variables declared in this block.

Computation of the sample mean and standard deviation: \overline{y} and s.

Transformed data block:

```
transformed data {
    real mean_y;
    real<lower=0> sd_y;
    mean_y = mean(y);
    sd_y = sd(y);
}
```

- Declaration and definition of 'constants'.
- Not reading from an external source.
- Assignments are only allowed to variables declared in this block.
- Constraints for checking.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

Parameters block:

▶ The parameters are being sampled by Stan.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

- ▶ The parameters are being sampled by Stan.
- ▶ Only declaration, no statement.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

- ▶ The parameters are being sampled by Stan.
- Only declaration, no statement.
- Variable constraints are very important.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

- ▶ The parameters are being sampled by Stan.
- Only declaration, no statement.
- Variable constraints are very important.
- ► To sample efficiently, any parameter values satisfying the constraints must have support in the model block (i.e., must have non-zero posterior density).

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

- ▶ The parameters are being sampled by Stan.
- Only declaration, no statement.
- Variable constraints are very important.
- ➤ To sample efficiently, any parameter values satisfying the constraints must have support in the model block (i.e., must have non-zero posterior density).
- ▶ Parameter ↔ unconstrained variable behind the scene.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

If we want to monitor the variance, we could do (but not efficient):

Transformed parameters block:

Declaration followed by statements.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

If we want to monitor the variance, we could do (but not efficient):

• Transformed parameters block:

- Declaration followed by statements.
- Part of the output.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

If we want to monitor the variance, we could do (but not efficient):

• Transformed parameters block:

- Declaration followed by statements.
- Part of the output.
- Constraints for checking.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

If we want to monitor the variance, we could do (but not efficient):

Transformed parameters block:

- Declaration followed by statements.
- Part of the output.
- Constraints for checking.
- ▶ Not efficient to declare here if you do not use in the model block.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

• Model block:

▶ Defining $p(\theta|y)$: prior and likelihood.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

• Model block:

- ▶ Defining $p(\theta|y)$: prior and likelihood.
- ▶ Optional variable declarations followed by statements.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

• Model block:

- ▶ Defining $p(\theta|y)$: prior and likelihood.
- Optional variable declarations followed by statements.
- ▶ The declared variables are local, not part of the output.

The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

• Model block:

- ▶ Defining $p(\theta|y)$: prior and likelihood.
- Optional variable declarations followed by statements.
- ▶ The declared variables are local, not part of the output.
- If we do not specify a prior, flat prior is automatically used.

The skewness discrepancy for replicate data $\frac{\sum_{i=1}^{N}((y_{i}^{rep}-\overline{y^{rep}})/s^{rep})^{3}}{N}$

• Generated quantities block:

```
generated quantities {
   vector[N] rep_y;
   real skewness_test;
   for (i in 1:N) {
       rep_y[i] = normal_rng(beta[1] + beta[2] * x[i], sigma);
   }
   skewness_test = step(skewness(rep_y) - skewness(y));
}
```

- ► Applications of posterior inference:
 - ★ Generate simulated data for model checking,

The skewness discrepancy for replicate data $\frac{\sum_{i=1}^{N}((y_{i}^{rep}-\overline{y^{rep}})/s^{rep})^{3}}{N}$

• Generated quantities block:

```
generated quantities {
   vector[N] rep_y;
   real skewness_test;
   for (i in 1:N) {
       rep_y[i] = normal_rng(beta[1] + beta[2] * x[i], sigma);
   }
   skewness_test = step(skewness(rep_y) - skewness(y));
}
```

- ► Applications of posterior inference:
 - ★ Generate simulated data for model checking,
 - * generate predictions for new data,

The skewness discrepancy for replicate data $\frac{\sum_{i=1}^{N}((y_i^{rep}-\overline{y^{rep}})/s^{rep})^3}{N}$

Generated quantities block:

```
generated quantities {
   vector[N] rep_y;
   real skewness_test;
   for (i in 1:N) {
       rep_y[i] = normal_rng(beta[1] + beta[2] * x[i], sigma);
   }
   skewness_test = step(skewness(rep_y) - skewness(y));
}
```

- ► Applications of posterior inference:
 - ★ Generate simulated data for model checking,
 - ★ generate predictions for new data,
 - * calculate posterior probabilities,

The skewness discrepancy for replicate data $\frac{\sum_{i=1}^{N}((y_{i}^{rep}-\overline{y^{rep}})/s^{rep})^{3}}{N}$

• Generated quantities block:

```
generated quantities {
   vector[N] rep_y;
   real skewness_test;
   for (i in 1:N) {
       rep_y[i] = normal_rng(beta[1] + beta[2] * x[i], sigma);
   }
   skewness_test = step(skewness(rep_y) - skewness(y));
}
```

- Applications of posterior inference:
 - ★ Generate simulated data for model checking,
 - ★ generate predictions for new data,
 - ★ calculate posterior probabilities,
 - ★ calculate (log) likelihoods, deviances, etc. for model comparison,

۲,

- Generated quantities block:
 - Can use global variables declared in earlier blocks.
 - When possible, define here is more efficient than in the transformed parameters block.
 - Generated quantities are parts of the output.
 - Constraints must succeed or sampling will be halted altogether because it is too late to reject a draw at the point the generated quantities block is evaluated.

Functions block

- Define a repeatedly used function.
- A function computing the skewness of a vector.

```
functions {
    real skewness(vector x){
        int N = num_elements(x);
        vector[N] m3;
        real skewness;
        for (i in 1 : N){
            m3[i] = ((x[i]-mean(x))/sd(x))^3;
        skewness = sum(m3)/N;
        return skewness;
```

- Exceptionally, variables declared in the model block are always local.
- Variables declared as function parameters have scope only within that function definition's body.

Data Types and Variable Declarations

• Every variable must have a declared data type.

• Only values of that type will be assignable to the variable.

• Two primitive types:

- Two primitive types:
 - int for integer values ($[-2^{31}, 2^{31} 1]$).

- Two primitive types:
 - ▶ int for integer values ($[-2^{31}, 2^{31} 1]$).
 - real for continuous values ($[-2^{1022}, 2^{1022}]$),

- Two primitive types:
 - ▶ int for integer values ($[-2^{31}, 2^{31} 1]$).
 - ightharpoonup real for continuous values ([-2^{1022} , 2^{1022}]),
- Three vector and matrix types:

- Two primitive types:
 - ▶ int for integer values ($[-2^{31}, 2^{31} 1]$).
 - real for continuous values ($[-2^{1022}, 2^{1022}]$),
- Three vector and matrix types:
 - vector for column vectors,

- Two primitive types:

 - real for continuous values ($[-2^{1022}, 2^{1022}]$),
- Three vector and matrix types:
 - vector for column vectors,
 - row_vector for row vectors,
 - matrix for matrices.
- Array types, e.g.
 - real x[10] declares x to be a one-dimensional array of size 10 containing real values.
 - matrix[3, 3] m[6, 7] declares m to be a two-dimensional array of size 6×7 containing values that are 3×3 matrices.

• Arrays are the only way to store sequences of integers.

- Arrays are the only way to store sequences of integers.
- Vectors and matrices versus arrays are not assignable to one another, even if their dimensions are identical.

- Arrays are the only way to store sequences of integers.
- Vectors and matrices versus arrays are not assignable to one another, even if their dimensions are identical.
- Vectors, matrices, and arrays are accessed by indexes.

- Arrays are the only way to store sequences of integers.
- Vectors and matrices versus arrays are not assignable to one another, even if their dimensions are identical.
- Vectors, matrices, and arrays are accessed by indexes.
- Their sizes are integer expressions.

• All of the basic data types may be given lower and upper bounds:

```
int<lower = 1> N;
real<upper = 0> log_p;
vector<lower = -1, upper = 1>[3] rho;
```

• All of the basic data types may be given lower and upper bounds:

```
int<lower = 1> N;
real<upper = 0> log_p;
vector<lower = -1, upper = 1>[3] rho;
```

Bounds for integer or real variables may be arbitrary expressions:

```
real<lower=min(y), upper=max(y)> phi;
```

Special data types for structured vectors and matrices

- Four constrained vector data types:
 - simplex for unit simplexes,
 - unit_vector for unit-length vectors, i.e. norm is 1,
 - ordered for ordered vectors of scalars,
 - positive_ordered for vectors of positive ordered scalars.

Special data types for structured vectors and matrices

- Four constrained vector data types:
 - simplex for unit simplexes,
 - unit_vector for unit-length vectors, i.e. norm is 1,
 - ordered for ordered vectors of scalars,
 - positive_ordered for vectors of positive ordered scalars.
- Specialized matrix data types:
 - corr_matrix for correlation matrices,
 - cov_matrix for covariance matrices (symmetric, positive definite),
 - cholesky_factor_cov for Cholesky factors of covariance matrices,
 - cholesky_factor_corr for Cholesky factors of correlation matrices.

Roles of constrained data types:

Roles of constrained data types:

 Data checking in the data, transformed data, transformed parameter, and generated quantities block.

Roles of constrained data types:

 Data checking in the data, transformed data, transformed parameter, and generated quantities block.

 Transformation determination from constrained variables to unconstrained variables.

Roles of constrained data types:

 Data checking in the data, transformed data, transformed parameter, and generated quantities block.

 Transformation determination from constrained variables to unconstrained variables.

Constraints.

• Integer and real: type + (optional) <constraint> + name

int n[5];
real a[3, 4];
real<lower=0> z[5, 4, 2];
vector[7] mu[3];
matrix[7, 2] mu[15, 12];
```

Exercise 2: Data types and constraint

- Which data types are used in Ex1?
- Which constraints are used and why?
- What happens if real sigma; or real<upper=0> sigma; ?
- Can we specify real<lower=1.0> sigma; ?

Exercise 3: Declaration

The folder Ex3 contains a data having two variables, x and y. We fit a simple linear regression model with y the response and x the covariate. This exercise is different from the Ex1 as we put the intercept covariate (1) and x into a matrix of two columns. The Stan program has one missing declaration.

- Run R and adapt the program following the Stan's error message.
- How do we change the program (R and Stan) if we have 2 covariates, x1 and x2?

Exercise 3: Declaration

The folder Ex3 contains a data having two variables, x and y. We fit a simple linear regression model with y the response and x the covariate. This exercise is different from the Ex1 as we put the intercept covariate (1) and x into a matrix of two columns. The Stan program has one missing declaration.

- Run R and adapt the program following the Stan's error message.
- How do we change the program (R and Stan) if we have 2 covariates, x1 and x2?
- How if we have $p \ge 3$ covariates?

Rules for naming:

• Case sensitive.

- Case sensitive.
- A declared name cannot be identical with a reserved name (See the manual).

- Case sensitive.
- A declared name cannot be identical with a reserved name (See the manual).
- A name is an ASCII strings containing only the basic lower-case and upper-case letters, digits, and the underscore (_) character.
- Variables must start with a letter (a-z and A-Z) and may not end with two underscores (__).

- Case sensitive.
- A declared name cannot be identical with a reserved name (See the manual).
- A name is an ASCII strings containing only the basic lower-case and upper-case letters, digits, and the underscore (_) character.
- Variables must start with a letter (a-z and A-Z) and may not end with two underscores (__).
- Examples of legal names:a, a3, a_3, Sigma, my_cpp_style_variable.

- Case sensitive.

 - multivariate function parameters and outcomes (e.g., multivariate normal distribution arguments).
- Vectors and matrices cannot be typed to return integer values. They
 are restricted to real values.
- Note: real values are never demoted to integers.

Compound Variable Declaration and Definition

 Stan allows assignable variables to be declared and defined in a single statement.

```
int N = num_elements(x);
```

Compound Variable Declaration and Definition

 Stan allows assignable variables to be declared and defined in a single statement.

```
int N = num_elements(x);
```

 Assignable variables are local variables and variables declared in the transformed data, transformed parameters, or generated quantities blocks.

```
int p = 5;
```

Compound Variable Declaration and Definition

 Stan allows assignable variables to be declared and defined in a single statement.

```
int N = num_elements(x);
```

 Assignable variables are local variables and variables declared in the transformed data, transformed parameters, or generated quantities blocks.

```
int p = 5;
```

 The right-hand side may be any expression which has a type being assignable to the variable being declared.

```
matrix[3, 2] A = 0.5 * (B + C);
```

Vector, matrix, and array expressions

ullet Use [] for vectors and matrices, and $\{\ \}$ for arrays.

```
row_vector[2] rv2 = [ 1, 2 ];
vector[3] v3 = [ a, b, c ]';
matrix[3,2] m1 = [ [ 1, 2 ], [ 3, 4 ], [5, 6 ] ];
int b[2, 3] = { { 1, 2, 3 }, { 4, 5, 6 } };
```

 Integer and real: addition (+), subtraction (-), negation (-), multiplication (*) and division (/) as usual.

- Integer and real: addition (+), subtraction (-), negation (-), multiplication (*) and division (/) as usual.
- Integer: modulus (%).

- Integer and real: addition (+), subtraction (-), negation (-), multiplication (*) and division (/) as usual.
- Integer: modulus (%).
- Integer and real: Exponentiation ^, returning a real value.

- Integer and real: addition (+), subtraction (-), negation (-), multiplication (*) and division (/) as usual.
- Integer: modulus (%).
- Integer and real: Exponentiation ^, returning a real value.
- Vector, row vector, matrix: addition, subtraction, negation, and multiplication as usual. Transpose operation using an apostrophe (').

- Integer and real: addition (+), subtraction (-), negation (-), multiplication (*) and division (/) as usual.
- Integer: modulus (%).
- Integer and real: Exponentiation ^, returning a real value.
- Vector, row vector, matrix: addition, subtraction, negation, and multiplication as usual. Transpose operation using an apostrophe (').
- Vector, row vector, matrix: Element-wise multiplication and division operations, a .* b and a ./b, but not better than for loop.

- Integer and real: addition (+), subtraction (-), negation (-), multiplication (*) and division (/) as usual.
- Integer: modulus (%).
- Integer and real: Exponentiation ^, returning a real value.
- Vector, row vector, matrix: addition, subtraction, negation, and multiplication as usual. Transpose operation using an apostrophe (').
- Vector, row vector, matrix: Element-wise multiplication and division operations, a .* b and a ./b, but not better than for loop.
- Return types for vector and matrix operations are the smallest types that can be statistically guaranteed to contain the result.

- Integer and real: addition (+), subtraction (-), negation (-), multiplication (*) and division (/) as usual.
- Integer: modulus (%).
- Integer and real: Exponentiation ^, returning a real value.
- Vector, row vector, matrix: addition, subtraction, negation, and multiplication as usual. Transpose operation using an apostrophe (').
- Vector, row vector, matrix: Element-wise multiplication and division operations, a .* b and a ./b, but not better than for loop.
- Return types for vector and matrix operations are the smallest types that can be statistically guaranteed to contain the result.
- See Chapter 43 for a complete list of operators.

Exercise 4: Arithmetic and matrix operations

Let k is of type int or real, y and mu are of type vector and Sigma is of type matrix. Which return type of the following expressions:

- k * y
- k * v'
- k + Sigma
- k * Sigma
- (y mu)'
- y'*y
- (y mu)' * Sigma * (y mu)

Operator Precedence and Associativity

Ор.	Prec.	Assoc.	Placement	Description
?:	10	right	ternary infix	conditional
	9	left	binary infix	logical or
&&	8	left	binary infix	logical and
==	7	left	binary infix	equality
!=	7	left	binary infix	inequality
<	6	left	binary infix	less than
<=	6	left	binary infix	less than or equal
>	6	left	binary infix	greater than
>=	6	left	binary infix	greater than or equal
+	5	left	binary infix	addition
-	5	left	binary infix	subtraction
*	4	left	binary infix	multiplication
/	4	left	binary infix	(right) division
%	4	left	binary infix	modulus
	3	left	binary infix	left division
.*	2	left	binary infix	elementwise multiplication
./	2	left	binary infix	elementwise division
1	1	n/a	unary prefix	logical negation
-	1	n/a	unary prefix	negation
+	1	n/a	unary prefix	promotion (no-op in Stan)
^	0.5	right	binary infix	exponentiation
,	0	n/a	unary postfix	transposition
()	0	n/a	prefix, wrap	function application
[]	0	left	prefix, wrap	array, matrix indexing

Operator precedence and associativity

• Precedence: smaller precedence has higher priority, e.g.

```
a+b*c is interpreted as a+(b*c), u*v' as u*(v').
```

Operator precedence and associativity

Precedence: smaller precedence has higher priority, e.g.

```
a+b*c is interpreted as a+(b*c), u*v, as u*(v).
```

• Same precedence: follow associativity.

Operator precedence and associativity

• Precedence: smaller precedence has higher priority, e.g.

```
a+b*c is interpreted as a+(b*c), u*v' as u*(v').
```

- Same precedence: follow associativity.
- Parentheses are recommended. Only () is allowed.

 Vectors, matrices, and arrays are accessed by indexes using the same array-like notation.

 Vectors, matrices, and arrays are accessed by indexes using the same array-like notation.

```
If vector[3] \ v3 = [ a, b, c ]'; \ v3[2] = b;
If matrix[3,2] \ m1 = [ [ 1, 2 ], [ 3, 4 ], [ 5, 6 ] ]; \ m1[2, 1] = 3
If int \ b[2, 3] = \{ \{ 1, 2, 3 \}, \{ 4, 5, 6 \} \}; \ b[2, 3] = 6
```

 Subscripting has higher precedence than any of the arithmetic operations, e.g.

```
alpha*x[1] is equivalent to alpha*(x[1]).
```

 Vectors, matrices, and arrays are accessed by indexes using the same array-like notation.

```
If vector[3] \ v3 = [ a, b, c ]'; \ v3[2] = b;
If matrix[3,2] \ m1 = [ [ 1, 2 ], [ 3, 4 ], [ 5, 6 ] ]; \ m1[2, 1] = 3
If int \ b[2, 3] = \{ \{ 1, 2, 3 \}, \{ 4, 5, 6 \} \}; \ b[2, 3] = 6
```

 Subscripting has higher precedence than any of the arithmetic operations, e.g.

```
alpha*x[1] is equivalent to alpha*(x[1]).
```

Indexes can be multiple.

 Vectors, matrices, and arrays are accessed by indexes using the same array-like notation.

```
If vector[3] \ v3 = [ a, b, c ]'; \ v3[2] = b;
If matrix[3,2] \ m1 = [ [ 1, 2 ], [ 3, 4 ], [ 5, 6 ] ]; \ m1[2, 1] = 3
If int \ b[2, 3] = \{ \{ 1, 2, 3 \}, \{ 4, 5, 6 \} \}; \ b[2, 3] = 6
```

 Subscripting has higher precedence than any of the arithmetic operations, e.g.

```
alpha*x[1] is equivalent to alpha*(x[1]).
```

- Indexes can be multiple.
- Expressions are allowed for indexes.

For matrix, col(matrix x, int n) returns the n-th column of x and row(matrix x, int m) returns the m-th row of x, a row_vector. A shorthand for row(matrix x, int m) is x[m].

example	row index	column index	result type
a[i]	single	n/a	row vector
a[is]	multiple	n/a	matrix
a[i, j]	single	single	real
a[i, js]	single	multiple	row vector
a[is, j]	multiple	single	vector
a[is, js]	multiple	multiple	matrix

Figure 4.3: Special rules for reducing matrices based on whether the argument is a single or multiple index. Examples are for a matrix a, with integer single indexes i and j and integer array multiple indexes is and js. The same typing rules apply for all multiple indexes.

• Multiple indexes can be integer arrays of indexes, lower bound 3:, upper bound :5, lower and upper bounds 2:7.

Exercise 5: Indexing

Given
$$A=\begin{bmatrix}1&2&3\\4&5&6\\7&8&9\end{bmatrix}$$
 , which (indexing) operator is used to produce the following results?

3,
$$\begin{bmatrix} 4 & 5 & 6 \end{bmatrix}$$
, $\begin{bmatrix} 2 & 3 \\ 5 & 6 \\ 8 & 9 \end{bmatrix}$, $\begin{bmatrix} 7 \\ 8 \\ 9 \end{bmatrix}$, $\begin{bmatrix} 5 & 8 \\ 6 & 9 \end{bmatrix}$.

We will use Stan to check your solution later.

(L-BioStat)

Exercise 6: Ex3 with p covariates

The folder Ex6 contains the same data as in the Ex3. We re-fit the linear regression model in that exercise.

- Re-write beta[1] * x[i, 1] + beta[2] * x[i, 2] in the Stan program as a product of a row vector and a vector. Note that x[i, 1] and x[i, 2] are the elements of the i^{th} row of x.
- Run the program.
- ullet Replace 2 by p and adapt the program.
- In R, add one more covariate in x, adapt R code, and re-run the program.

Exercise 7: Ex6 with an array for x

The folder Ex7 contains the same data and programs as in the previous exercise except that we declare x using an array.

- Declare x as an one-dimensional array of size N where its elements are vectors of length p.
- Adapt the Stan program and run it.

Statements

• Blocks = declarations + statements.

Statements

- Blocks = declarations + statements.
- Assignment statement:

```
Sigma = diag_matrix(sigma) * Omega * diag_matrix(sigma);
```

Statements

- Blocks = declarations + statements.
- Assignment statement:

```
Sigma = diag_matrix(sigma) * Omega * diag_matrix(sigma);
```

Compound arithmetic and assignment statement:

Operation	Compound	Long
addition	x += y	x = x + y
subtraction	x -= y	x = x - y
multiplication	x *= y	x = x * y
division	x /= y	x = x / y
elementwise multiplication	x .*= y	x = x .* y
elementwise division	x ./= y	$x = x \cdot / y$

Figure 5.1: Stan allows compound arithmetic and assignment statements of the forms listed in the table above. The compound form is legal whenever the corresponding long form would be legal and it has the same effect.

• The most important statement, defining the target.

- The most important statement, defining the target.
- Just a notation, no sampling performance.

```
y[i] ~ normal(mu, sigma);
```

- The most important statement, defining the target.
- Just a notation, no sampling performance.

```
y[i] ~ normal(mu, sigma);
```

Expressed as an increment on the total log probability

```
target += normal_lpdf(y | mu, sigma);
```

- The most important statement, defining the target.
- Just a notation, no sampling performance.

```
y[i] ~ normal(mu, sigma);
```

Expressed as an increment on the total log probability

```
target += normal_lpdf(y | mu, sigma);
```

• In general y ~ dist(theta); is expressed as

```
target += dist_lpdf(y \mid theta); if y is real and target += dist_lpmf(y \mid theta); if y is integer.
```

- The most important statement, defining the target.
- Just a notation, no sampling performance.

```
y[i] ~ normal(mu, sigma);
```

Expressed as an increment on the total log probability

```
target += normal_lpdf(y | mu, sigma);
```

• In general y ~ dist(theta); is expressed as

```
target += dist_lpdf(y \mid theta); if y is real and target += dist_lpmf(y \mid theta); if y is integer.
```

 Log probability increment vs. sampling statement: including vs excluding all constant terms.

• The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

• The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

• Combining with the prior, the posterior:

posterior
$$\propto f_{N(0,1000)}(\beta_1) \times f_{N(0,1000)}(\beta_2) \times f_{half-cauchy(0,5)}(\sigma)$$
$$\times \prod_{i=1}^N f_{N(\beta_1+\beta_2\times x_i,\sigma^2)}(y_i)$$

• The model:

$$y_i \sim N(\beta_1 + \beta_2 \times x_i, \sigma^2) \quad \forall i = 1, ..., N$$

• Combining with the prior, the posterior:

$$\begin{aligned} \text{posterior} & \propto \ f_{N(0,1000)}(\beta_1) \times f_{N(0,1000)}(\beta_2) \times f_{half-cauchy(0,5)}(\sigma) \\ & \times \prod_{i=1}^N f_{N(\beta_1+\beta_2 \times x_i,\sigma^2)}(y_i) \end{aligned}$$

Stan works with log scale:

$$\begin{split} \log \text{ post.} =& \log f_{N(0,1000)}(\beta_1) + \log f_{N(0,1000)}(\beta_2) + \log f_{half-cauchy(0,5)}(\sigma) \\ &+ \sum_{i=1}^N \log f_{N(\beta_1+\beta_2\times x_i,\sigma^2)}(y_i) + \text{a constant} \end{split}$$

- 4 ロト 4 個 ト 4 恵 ト 4 恵 ト - 恵 - 夕 Q (C)

• What we see:

```
model {
   beta ~ normal(0, 1000);  // prior
   sigma ~ cauchy(0, 5);  // half-cauchy implicitly
   for (i in 1:N) {
      y[i] ~ normal(beta[1] + beta[2] * x[i], sigma);
   }
}
```

Behind the scene (C++):

Stan language	Translated
beta ~ normal(0, 1000)	$\begin{array}{l} target = 0 \; (initialization) \\ target \; + = \; normal_lpdf(beta[1] \; \; 0, 1000) \\ target \; + = \; normal_lpdf(beta[2] \; \; 0, 1000) \end{array}$
sigma ~ cauchy(0, 5)	$target \mathrel{+}= cauchy_lpdf(sigma \mid 0,5)$
$\begin{array}{c} \textbf{y[i]} & \sim \textbf{normal(beta[1]} + \textbf{beta[2]} \\ \textbf{*} \textbf{x[i], sigma)} \end{array}$	$\begin{array}{l} target \mathrel{+}= normal_lpdf(y[i] \mid beta[1] + beta[2] * \\ x[i], sigma) \end{array}$

• Finally, target = log post. (+ a constant)

- Having higher precedence than any of the others.
- Type signature requirement: input and output type.
- Uniquely determined by its name and its sequence of argument types.
 Thus, real mean(real[]); and real mean(vector); are different.
- Constants have no arguments, e.g. pi().

Important built-in functions of a distribution

If dist() is a distribution then

- dist_lpdf a function computing the log probability density if it is continuous.
- dist_lpmf a function computing the log probability mass if it is discrete.
- dist_rng a function generating a variate.
- See the manual for more detail.

• Similar to R but explicitly requires input and output types, e.g.

• Similar to R but explicitly requires input and output types, e.g.

```
real foo(real a, real b) {
    return a+b;
}
```

Must have a return as the last statement.

Similar to R but explicitly requires input and output types, e.g.

```
real foo(real a, real b) {
    return a+b;
}
```

- Must have a return as the last statement.
- Last but not last! Be careful when use loop or condition. This is not qualified:

```
real foo(real x) {
    if (x > 2) return 1.0;
    else if (x <= 2) return -1.0;
}</pre>
```

since no default else statement.

Similar to R but explicitly requires input and output types, e.g.

```
real foo(real a, real b) {
    return a+b;
}
```

- Must have a return as the last statement.
- Last but not last! Be careful when use loop or condition. This is not qualified:

```
real foo(real x) {
    if (x > 2) return 1.0;
    else if (x <= 2) return -1.0;
}</pre>
```

since no default else statement.

The functions block is placed before the data block.

- Function names follow naming rules.
- Arguments are mandatory, no default values.
- Functions are only declared for base type (integer, real, vector, row_vector, and matrix) and dimensionality.
- No size and no constraints (lower-bound, upper-bound, or specialized types).

```
real skewness(vector x){
    int N = num_elements(x); // local variable,
    ... // others in the function body
}

matrix new_psi_fun(real psi, real t) {
    matrix[2, 2] output; // local variable
    output[1, 1] = psi^t;
    ...
    return output;
}
```

More details, see Sections 7 and 24 in the manual.

66 / 98

The Ex9 contains a Stan program to define the following function: Input is a vector and output is a diagonal matrix where the vector lies along the diagonal.

Definition: matrix my_func(vector x).

- Definition: matrix my_func(vector x).
- Declare a local matrix to store the elements of the output.

- Definition: matrix my_func(vector x).
- Declare a local matrix to store the elements of the output.
- Use for loop and if-else condition to define the matrix.

$$A_{ij} = \begin{cases} 0 \text{ if } i \neq j \\ x_i \text{ otherwise} \end{cases}$$

- Define that function in the functions block of the Stan program.
- Use print statement to check your program.

- Definition: matrix my_func(vector x).
- Declare a local matrix to store the elements of the output.
- Use for loop and if-else condition to define the matrix.

$$A_{ij} = \begin{cases} 0 \text{ if } i \neq j \\ x_i \text{ otherwise} \end{cases}$$

- Define that function in the functions block of the Stan program.
- Use print statement to check your program.
- Check whether the manual having a built-in function doing the same.

- Summary

Working with R

 Monitor parameters from parameters, transformed parameters, and generated quantities block.

```
stan(..., pars = c('beta', 'sigma'), ...)
```

Convergence diagnosis using trace plots

```
stan_trace(model1a, pars = 'beta', inc_warmup = T)
stan_trace(model1a, pars = 'sigma', inc_warmup = T)
```

Saving trace plots

```
windows()
stan_trace(model1a, pars=c('beta'), inc_warmup = F)
savePlot('Rplot_beta', type = 'pdf')
```

- Formal convergence diagnosis by Rhat and effective sample size. summary (model1a) \$summary
- Final summary.

```
summary(model1a)$summary
```

ShinyStan

A powerful package for visualization and more

library(shinystan)

launch_shinystan(model1a)

Exercise 10: Shinystan

The folder Ex10 contains a program to explore shinystan.

- Run the program in R.
- Run shinystan and check convergence using the DIAGNOSE tab.
- Explore more shinystan features.

rstanarm

Applied Regression Modeling via RStan

 Allow regression models to be specified using the customary R modeling syntax.

rstanarm

Applied Regression Modeling via RStan

- Allow regression models to be specified using the customary R modeling syntax.
- Similar syntax as Im and glm in stats package.

```
stan_lm(formula, data, subset, weights, na.action, model = TRUE, x = FALSE,
y = FALSE, singular.ok = TRUE, contrasts = NULL, offset, ...,
prior = R2(stop("'location' must be specified")), prior_intercept = NULL,
prior_PD = FALSE, algorithm = c("sampling", "meanfield", "fullrank"),
adapt_delta = NULL)
```

lm(formula, data, subset, weights, na.action,
method = "qr", model = TRUE, x = FALSE, y = FALSE,
qr = TRUE, singular.ok = TRUE, contrasts = NULL, offset, ...)

- Many examples are given in the manual and the Stan website.
- Keep in mind that Stan also has some limitations:
 - No discrete parameters.
 - No implicit missing data (code as parameters).

Some differences from BUGS

	Stan	BUGS	
Sampling	All at a time	One at a time	
Statement order	A matter	Does not matter	
Gradients	Required	Not required	
Naming	Full stop not possible	Full stop not possible	
Normal distribution	Standard deviation	Precision	
Distribution nota-	normal, poisson	dnorm, dpois	
tion Reassignment of lo- cal variables	Allow	Not allow	
Discrete parameters	Not allow yet	Allow	
Implicit flat prior	Yes	No	
Conjugacy	No computational advantage	Yes	

More efficient coding

In some situations, the following coding might be more efficient

- Vectorization vs for loop.
 - For loop
 for (i in 1:N) {
 y[i] ~ normal(beta[1] + beta[2] * x[i], sigma);
 - Vectorization

```
y ~ normal(beta[1] + beta[2] * x, sigma);
```

 Time comparison between for loop and vectorization, measured in second.

Sample size	For loop	Vecterization	Ratio
5000	2.587	1.555	1.664
50000	43.987	24.180	1.819
200000	182.345	131.761	1.384
500000	494.569	372.416	1.328

More efficient coding

• Centered versus non-centered parameterization.

Center

```
parameters {
  real y;
  vector[9] x;
}
model {
  y ~ normal(0, 3);
  x ~ normal(0, exp(y/2));
}
```

Non-centered

```
parameters {
    real y_raw;
    vector[9] x_raw;
}
transformed parameters {
    real y;
    vector[9] x;
    y = 3.0 * y_raw;
    x = exp(y/2) * x_raw;
}
model {
    y_raw ^ normal(0, 1); // implies y ^ normal(0, 3)
    x_raw ^ normal(0, 1); // implies x ^ normal(0, exp(y/2))
```

Some suggestions

• Start writing from the model block.

- Start writing from the model block.
- Build up with data and parameters blocks, then other blocks.

- Start writing from the model block.
- Build up with data and parameters blocks, then other blocks.
- Choose priors (BUGS prior might not the best since Stan does not require conjugacy).

- Summary

Ex11: Posterior predictive check (PPC) for the linear regression model

This exercise, in the folder Ex11, is for checking whether the linear regression model in Exercise 3 is appropriate for that data.

- Use the built-in function normal_rng(mu, sigma) to generate the replicate.
- Using Shinystan to visualize the distribution of the response and the replicate.

Ex12: A logistic regression model

In the folder Ex12, the file Ex12.txt contains the data with two variables, x and y where y is binary and x is continuous. The logistic regression model, y is regressing on x, is given in model_Ex12.stan.

- What is the type of y and why?
- Run the program.

Ex12: A logistic regression model

In the folder Ex12, the file Ex12.txt contains the data with two variables, x and y where y is binary and x is continuous. The logistic regression model, y is regressing on x, is given in model_Ex12.stan.

- What is the type of y and why?
- Run the program.
- Compute P(y=1|x=1) in the generated quantities block.
- In the program, the print statement prints the probability to the console. Adapt the Stan program so that you can monitor that probability in R. Adapt R code to obtain the output.

Ex13: A longitudinal analysis for balanced data. An AR structure

The folder Ex13 contains a balanced longitudinal data collected for N=30 individuals, each has T=4 repeated measurements. Let y_{ij} is the response for the individual i (i=1,...,N) at time point j (j=1,...,T). Denote $\boldsymbol{y}_i=(y_{i1},...,y_{iT})^T$. The covariates are x and time. Fit the following model:

$$\boldsymbol{y}_i \sim N(\boldsymbol{\mu}_i, \boldsymbol{\Sigma})$$

where $\mu_{ij}=\beta_1+\beta_2\times x_i+\beta_3\times time_j+\beta_4\times x_i\times time_j$ and Σ has an autoregressive structure, i.e. $\Sigma_{ij}=\sigma\times \rho^{|i-j|}$, where $\sigma\geq 0$ and $0\leq\rho\leq 1$ are two parameters.

- ullet The incomplete Stan program uses two for loops to define Σ in the transformed parameters block. Complete the program.
- Is(Are) there any block(s) that we can define Σ ? If yes, adapt your program. Is there any difference between the adapted program(s) and the initial one?

Ex14: A linear mixed model

The folder Ex14 contains the data from the Ex13 one. A new ID is created in R, ranging from 1 to 30. Fit a random intercept model of the following form to the data in Ex13:

$$y_{ij} \sim N(\mu_{ij}, \sigma^2)$$
,

where $\mu_{ij} = \beta_1 + \beta_2 \times x_i + \beta_3 \times time_j + \beta_4 \times x_i \times time_j + b_i$ and $0 < \sigma$ is a parameter.

- Run the model.
- Extend the model to include a random slope.

- Summary

у	х
0.7008	0.6469
NA	-0.6993
0.3515	-1.3202

• Suppose now that y in Ex3 has some missing values:

У	X
0.7008	0.6469
NA	-0.6993
0.3515	-1.3202

• Unfortunately, Stan does not support NA in the data block.

X
0.6469
-0.6993
-1.3202

- Unfortunately, Stan does not support NA in the data block.
- Solutions:

У	X
0.7008	0.6469
NA	-0.6993
0.3515	-1.3202

- Unfortunately, Stan does not support NA in the data block.
- Solutions:
 - ▶ (i) Separate the observed part and missing part of *y* into appropriate blocks.

У	X
0.7008	0.6469
NA	-0.6993
0.3515	-1.3202

- Unfortunately, Stan does not support NA in the data block.
- Solutions:
 - (i) Separate the observed part and missing part of y into appropriate blocks.
 - Or, (ii) turn y into fully observed.

Solution (i): Missing data as parameters.

ullet Create an index and a missing indicator, then separate y:

Original				Observed part			Missing part				
No	У	×	mis_ind	No	у	×	mis_ind	No	у	×	mis_ind
1	0.7008	0.6469	0	1	0.7008	0.6469	0	2	NA	-0.6993	1
2	NA	-0.6993	1	3	0.3515	-1.3202	0				
3	0.3515	-1.3202	0								

- y is partitioned into y_{obs} and y_{mis} .
 - ▶ y_{obs} is declared in the data block.
 - y_{mis} is declared in the parameters block.
- y is merged in transformed parameters block.
- Several index arrays for partitioning and combining.

Preparing in R:

- Create an index if not available.
- Create a missing indicator: 0 if observed and 1 if missing.
- Partition the original data frame into two data frames, using the missing indicator.

```
Stan code: Partitioning
data {
    int<lower = 0> N_obs;
    int<lower = 0> N_mis;
    int<lower = 1, upper = N_obs + N_mis> id_obs[N_obs];
    int<lower = 1, upper = N_obs + N_mis> id_mis[N_mis];
    vector[N_obs] y_obs;
    vector[N_obs + N_mis] x; // covariate
}
transformed data {
    int<lower = 0> N = N_obs + N_mis; // sample size
```

```
Stan code: Combining
parameters {
    vector[N_mis] y_mis;
    vector[2] beta; // regression coefficients
    real<lower=0> sigma; // SD
transformed parameters {
    vector[N] y;
    y[id_obs] = y_obs;
   y[id_mis] = y_mis;
```

```
Stan code: Modeling
model {
    beta ~ normal(0, 1000); // prior
    sigma ~ cauchy(0, 5); // half-cauchy implicitly

    for (i in 1:N) {
        y[i] ~ normal(beta[1] + beta[2] * x[i], sigma);
    }
}
```

Solution (ii): Using "artificially imputed" data

Missing values are imputed by "implausible" values in R.

```
y_impute = NULL

for (i in 1 : N){
    if (data$mis_ind[i] == 0){y_impute[i] = data$y[i]}
        else y_impute[i] = 999
}
```

Replace missing values by imputed values.

• Use if statement in model block

```
for (i in 1:N) {
    if (mis_ind[i] == 0){
        y[i] ~ normal(beta[1] + beta[2] * x[i], sigma);
    }
}
```

Ex15: Dealing with missing values

The folder Ex15 contains the data taken from Ex3 with some missing values on y. Two programs for the two solutions are provided.

• Understand those programs.

Some notes on missing values

- Solution (i) only works with continuous response. Solution (ii) can be used for both continuous and discrete response.
- For missing covariates, the first can be extended and a sequence of imputation models are implemented as long as they are continuous.
- Both solutions may not be used for missing discrete covariates.
